A 5-step guide to go Zero Trust

The network perimeter is dissolving. Cloud-based data centers have abstracted the traditional data centers into dynamic, software-defined entities. The new data center is easy to deploy and destroy and is often managed using APIs and code.

On top of that, the remote workforce who increasingly uses their own devices for the sake of productivity, raises questions among security practitioners about the relevance of the castle-and-moat approach for keeping attackers outside the network perimeter.

The attempt to prevent attackers from getting into the network while allowing users to access remotely, has quickly turned into a lost cause, with red teams (and attackers) easily gaining the initial foothold inside the network, and freely moving laterally across the data center.

The Zero Trust approach is becoming more popular across security and operation teams as it can address many of the shortcomings of the traditional castle-and-moat approach. However, the interpretation of Zero Trust can vary between vendors, analysts, and security practitioners. Figuring out the right way for an organization to implement the Zero Trust model in its environment can be daunting and can prevent the organization from moving toward better security and simpler operations.

In this guide, we will discuss the five steps to achieving a Zero Trust access model in your environment.
Step #1
Figure out the right Identity and Access Management for your organization

The most basic building block of any modern access approach is the identity; just as the most common attack vector is compromised identity.

When building the Zero Trust security model, you must be able to trust the user’s authentication and based on that, provide access to the organization’s resources.

Critical elements for user authentication:

• Choose a “single source of truth” for your IAM where all users are authenticated and provided with the correct roles for authorization
• Enable MFA for the sensitive accounts; consider widening this to all accounts
• Have a clear logging and auditing mechanism for user’s authentication information
• Have in place a basic identity governance to manage the user’s role assignments and onboarding, role transitions, and offboarding within your IAM solution
Step #2

Differentiate managed and unmanaged devices used for access

Once we can trust the user’s authentication, we have to make sure that we tie the authentication to the user’s device. There’s a big difference between a user authenticating from a corporate-managed device, compliant with the organizational policies, versus the same user authenticating from their personal device without any security measures.

The ability to differentiate between managed and unmanaged devices is critical when looking into the context of the access request.

In more advanced scenarios, the device’s compliance, as well as any risk identified on the device (such as potential malware), can be leveraged to determine the level of access allowed for any given request.

Critical elements for user authentication:

- Have an up-to-date inventory of your managed devices
- Define access scenarios for managed versus unmanaged devices
- Select your endpoint security solution (EDR) to allow dynamic verification of the device compliance and security state

Figure out the right IAM solution

2

Differentiate managed and unmanaged devices

3

Map your access scenarios

4

Get a Zero Trust access platform

5

Migrate network-level access policies to Zero Trust
Step #3

Map your access scenarios

Dip your toe in the water first. Migrating the entire organization to a new access paradigm all at once is a task next to impossible. Such a process is likely to raise concerns from the different parties involved. To successfully implement Zero Trust, you will have to slowly build the stakeholders’ trust in the Zero Trust security model and tackle each concern as it comes. Luckily, the migration process can be easily managed in stages.

Start with an access scenario where the Zero Trust model will generate the biggest value and do this as quickly as possible.

Start with mapping the existing access scenarios. You can do this either by destination or by source: the destination being the resource that’s accessed and the source being the user and device accessing said resource.

A sample map could be similar to:

<table>
<thead>
<tr>
<th>By destination (resource)</th>
<th>By source (user/device)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud-based data centers (as part of a digital transformation project)</td>
<td>Remote and mobile workforce accessing corporate applications</td>
</tr>
<tr>
<td>Production IaaS and PaaS workloads across multiple cloud vendors and multiple data centers and regions</td>
<td>Third-party contractors and business partners using their own devices</td>
</tr>
<tr>
<td>Services hosting sensitive information, accessed remotely by employees</td>
<td>Engineers who require just-in-time privileged access to production servers</td>
</tr>
</tbody>
</table>

Now that you have a clear view of your organization’s different access scenarios, you can prioritize the ones which will benefit the most from the increased security and the reduced operational overhead, the two immediate results that you can expect from migrating to the Zero Trust access model.
Step #4

Get a Zero Trust access platform

Now it’s time to evaluate the different Zero Trust access platforms available on the market to see which one provides the best match for your specific requirements.

Some of the key criteria to consider based on your needs:

- **Should the platform be cloud-based or on-premises?** In most cases, a cloud-based solution, delivered as a service, would be the preferred choice due to reduced maintenance requirements as well as a lower TCO.

- **How well does the platform integrate with your existing IAM, Device Management/EDR, SIEM, and UEBA solutions?** Any Zero Trust access platform requires as much context as possible to provide the right access level at the right moment. The better the chosen platform integrates with your existing infrastructure, the more context it will have to perform the access decisions.

- **Do you need just access, or governance of the user’s actions?** Do you need a platform that only provides access to cloud-hosted and on-premise corporate resources, or would you want to govern the user’s activities when accessing the remote assets? If you wish to block SSH commands or downloads of sensitive files, or allow access to only a specific set of URIs, you need a Zero Trust platform which can provide both the access and the governance.
Step #5

Migrate network-level access policies to Zero Trust access policies

When you have your IAM, EDR, device inventory, and access scenarios all mapped out, and the Zero Trust technological platform selected, you can begin the transition to Zero Trust with the first access scenario identified.

As each application, service, and workload becomes accessible via your Zero Trust platform, you should immediately block all of the network-level access to it.

Your resources are then fully cloaked and isolated from both the internet and the user’s network and are accessible via the Zero Trust access platform only. This access is, of course, based on the user’s identity and the device.

Once your applications, servers, or workloads are fully isolated and cloaked, they are completely protected from lateral movement and network-level attacks, both of which are common attack vectors in multiple breaches.

Don’t forget your users

Your users, their satisfaction, and cooperation levels are critical to the success of this process. So before you hit the button, make sure the users understand how to access their corporate services, applications, and workloads and how to provide you with immediate feedback. Adding services and applications is easy and quick. Let your users appreciate and benefit from the new speed of your operation.

Validate the successful implementation of the access model via feedback sessions and interviews with your users.
Summary

To conclude, implementing a Zero Trust access model in your organization doesn’t require a complex, multi-year project. In today’s agile world, you can start with a simple access scenario built on the basics of identity and device, which most organizations already have.

Symantec Secure Access Cloud™

Symantec enables security and IT teams to create Zero Trust Application Access architecture without traditional VPN appliances. Symantec Secure Access Cloud™ securely connects any user from any device, anywhere in the world to corporate on-premises and cloud-hosted applications while all other corporate resources are cloaked. No network access is ever granted to prevent any lateral movements to other network resources while eliminating the risk of network-based attacks. The platform is agentless and can be deployed in less than five minutes, without forcing a disruptive change in the organization’s existing architecture, user permissions, and applications. Symantec Secure Access Cloud™ provides full governance and real-time enforcement of users’ actions in each corporate application.

About Symantec

Symantec Corporation (NASDAQ: SYMC), the world’s leading cyber security company, helps organizations, governments and people secure their most important data wherever it lives. Organizations across the world look to Symantec for strategic, integrated solutions to defend against sophisticated attacks across endpoints, cloud and infrastructure. Likewise, a global community of more than 50 million people and families rely on Symantec’s Norton and LifeLock product suites to protect their digital lives at home and across their devices. Symantec operates one of the world’s largest civilian cyber intelligence networks, allowing it to see and protect against the most advanced threats. For additional information, please visit www.symantec.com or connect with us on Facebook, Twitter, and LinkedIn.
